Allenstown Community Center 8 Whitten St. Allenstown, New Hampshire

PROJECT DESCRIPTION

The proposed project is located at 8 Whitten Street in the Town of Allenstown, New Hampshire. The project is situated on lot 112-267 which has an area of 1.741 acres and is owned by the Town of Allenstown. The parcel is known as the "Whitten Street Park" and is the current site of the Boys & Girls Club of Suncook.

The existing Boys & Girls Club site is comprised of two manufactured buildings, paved tennis and basketball courts, and parking accessed by a narrow driveway. The west part of the site slopes steeply down to Reynolds Street and is partially retained by a boulder wall. The aged existing facilities will be demolished to provide space for the new project.

The project includes construction of a new 9,400 square-foot two story building, parking both on the upper portion of the site and on Reynolds Street, a 20 ft wide access drive, sidewalks, a basketball court and associated landscaping, lighting and drainage improvements. The building will be sited on the existing steep slope facing Reynolds Street to provide ground level access to the first floor from Reynolds Street and to the second floor from the upper parking lot. The new Allenstown Community Center building will have a dual function of serving both the Boys & Girls Club and a senior center.

The drainage design was completed based on the USDA NRCS Web Soil Survey, which shows that the soils on the site and surrounding watersheds are Hydrological Soil Group (HSG) A soils. HSG A soils which have low runoff potential and high infiltration rates. The soil type associated with the site and surrounding neighborhood was identified as 598B, Windsor-Urban land complex, with 0 to 8 percent slopes.

The site poses some unique challenges such as a shallow groundwater table and is located within a groundwater management zone (GMZ), as defined by New Hampshire Department of Environmental Services Permit # GMP-198400003-A-003. Groundwater within the GMZ may contain dissolved gasoline-related compounds at concentrations greater than the ambient groundwater quality standards. The gasoline-related compounds are attributable to a release that occurred at the Former Bob's Citgo (circa 1972) which was located at the intersection of Main Street and Ferry Streets.

A closed municipal drainage system runs through the site from east to west starting on Main Street and terminating at an outfall into the river. A "Design Point" located on Reynolds Street was chosen for the watershed analysis. Design Point 1 includes runoff from watersheds collected by the upstream closed system, including stormwater from the existing Boys & Girls Club site which ties in to the Design Point, a 10 inch clay pipe running along Reynolds Street. Refer to the *Existing Conditions Narrative* and *Proposed Conditions Narrative* sections of this study for a detailed explanation of the Design Point under pre- and post-development conditions.

This study examines the hydraulic and hydrologic characteristics associated with the development of the proposed project. An analysis of the drainage impacts due to the construction of the project was completed. As a result, the proposed stormwater management system has been designed to best utilize the existing hydrologic and hydraulic patterns, minimize impacts to surrounding areas, and provide best management practices for water quality treatment measures.

Based on FEMA flood insurance rate map for Merrimack County community panel number 33013C0564E dated April 19, 2010, the parcel is not located within a 100-year or 500-year flood zone.

REPORT METHODOLOGY

The runoff analysis is based on analyzes of the 2, 10, 25, and 50-year 24-hour design storms using the SCS TR-55 method with Type-III, 24-hour storms. All runoff from this development is accounted for in the analysis presented.

The summaries and calculations for the peak pre- and post-development rates of runoff, supporting calculations and maps for the proposed project are included in this study.

On-site subcatchments were delineated from completed survey and GIS mapping. SCS Runoff Curve Numbers (CN) were developed for each area of generally similar properties within each Subcatchment. The nature of flow, flow length, type of surface (e.g. ground cover) and slope were characterized for each Subcatchment and reach (swale or pipe) to determine the time of concentration and maximum outflow rate. Soil types and Hydrologic Soil Groups were determined from the USDA NRCS Web Soil Survey data. A copy of the soil report is included in Appendix A.

DRAINAGE ANALYSIS METHODOLOGY

Technical Release 20 (TR-20) by the Natural Resources Conservation Service was utilized for modeling the surface water hydrology of the site. The model begins with a rainfall amount uniformly imposed on the watershed over a specified time distribution, 24 hours in this analysis. The mass rainfall is converted to mass runoff by using a Runoff CN. The determination of the CN is based on assessments of soil characteristics, vegetation type and condition, amount of impervious areas, interception and surface storage. The calculated runoff is then transformed into a hydrograph by using unit hydrograph theory and routing procedures that depend on runoff travel time through the individual segments of the watershed. Typically, various storage configurations and volumes are analyzed to adjust detention times and the hydrograph so that the downstream peak discharge is reduced to equal or less than pre-development conditions.

The analysis utilized the computerized TR-20 software as included in the HydroCAD package. Tabular hydrographs were generated for the following:

- 2-year event/24-hour duration
- 10-year event /24-hour duration
- 25-year event /24-hour duration
- 50-year event/24-hour duration

Time of Concentration (T_c) for each sub-area was computed based on physical characteristics including surface type, Manning's Roughness Coefficient, flow length, 2-Year/24-Hour rainfall values, and gradients of the land.

TR-55 Analysis

The overall site pre- and post-development hydrographs were calculated utilizing the method detailed in Technical Release 55 (TR-55) "*Urban Hydrology for Small Watersheds*" as published by the United States Department of Agriculture Soil Conservation Service, "SCS", and revised in June of 1986. Tabular hydrographs were computed based on CN, T_c , T_t , area and precipitation input values. Rainfall precipitation data were also obtained from TR-55.

The SCS Method is based upon the SCS Runoff Equation:

$$Q = \frac{(P - I_a)^2}{(P - I_a) + S}$$

Where:

- Q = Runoff in Inches
- P = Rainfall in Inches
- S = Potential Maximum Retention in Inches
- I_a = Initial Abstraction in Inches

Note:

- S = $1000 / CN - 10$
- CN = Runoff Curve Number

Computations were executed using the "HydroCAD" release 9.10 for Windows computer software for storm sewer design and analysis from Applied Microcomputer System.

EXISTING CONDITIONS NARRATIVE

The 1.741-acre parcel is accessed by Whitten Street and has frontage along Reynolds Street along the western boundary. The northern boundary of the parcel generally abuts residential properties with frontage on Whitten Street. The southern boundary of the parcel generally abuts residential properties with frontage on Ferry Street. The eastern boundary abuts the Allentown Fire Station located on Ferry Street as well as other residential properties. The existing site is currently located at 8 Whitten Street and contains two manufactured buildings each with a footprint of approximately 1,500 square feet. The site also has associated parking, tennis and basketball courts, as well as areas of grass, brush and tree cover.

Design Point 1 is the 10 inch clay drainage pipe on Reynolds Street, which outlets from the existing drain manhole adjacent to the site (DMH-2). DMH-2 appears to be an old sewer manhole of approximately 100 years old as evidenced by the brick invert and based upon discussions with Public Works personnel. This drainage study assumes that all upstream structures located on Reynolds Street tie in to this 10 inch clay main though some catch basin structures have obscured outlet pipes and are not specifically modeled in this analysis.

The 10 inch clay main receives existing flow from a closed municipal drainage system which serves a watershed area of approximately 10 acres. As the hydrologic model in this report predicts, this pipe is currently undersized for the 10 year, 24 hour storm but no known reports of backup in the system have been received by the Town.

The USDA NRCS Web Soil Survey determined that the existing on-site soils include Windsor-Urban land complex (Hydrologic Soil Group A). The existing ground cover includes impervious surfaces due to the existing building, parking lot, tennis and basketball courts, residential structures and pavement as well as some roadway drainage. A detailed and tabular summary of the flows associated with each existing Design Point can be found in the *Pre Development Analysis Criteria* section of this study.

A Pre-Development Watershed Map is included in Appendix D.

PRE-DEVELOPMENT ANALYSIS CRITERIA

The complete HydroCAD analysis for pre-development conditions is included in Appendix B. Rainfall precipitation data was obtained TR-55. The analysis criteria used for the SCS TR-20 hydraulic analysis of the pre-development conditions are as follows:

- Storm Event Frequency: 2, 10, 25, and 50 year, 24-hr storms
- Storm (yr, 24-hr) Rainfall Depth (inches)

2	2.90
10	4.40
25	5.00
50	5.50
- Runoff Coefficients (CN)

>75% grass cover, good, HSG A	= 39
2 acre lots, 12% impervious, HSG A	= 46
1 acre lots, 20% impervious, HSG A	= 51
½ acre lots, 25% impervious, HSG A	= 54
¼ acre lots, 38% impervious, HSG A	= 61
Pavement, roofs, parking lots	= 98

SCS TR-20 Analysis

The pre development peak discharge from the project area for 2, 10, 25, and 50-year 24-hour design storms frequencies of 24-hour duration is:

Analysis Point	Inflow Area	2-year Storm	10-year Storm	25-year Storm	50-year Storm
	Acres	Flow (cfs)	Flow (cfs)	Flow (cfs)	Flow (cfs)
Design Point 1	9.3	0.8	5.0	7.7	10.1

PROPOSED CONDITIONS NARRATIVE

The proposed Allenstown Community Center project will include the demolition of all existing impervious surfaces including buildings and parking lot, tennis and basketball courts and access drive. New impervious surfaces to be constructed include the proposed building, parking, an access drive and basketball court. A Post-Development Watershed Map is included in Appendix D.

Under proposed conditions, Design Point 1 contains generally the same overall watershed as the pre-development conditions but has improved stormwater routing on the site and on Reynolds Street.

All stormwater runoff from the site is captured within the closed municipal drainage system.

POST-DEVELOPMENT ANALYSIS CRITERIA

The complete HydroCAD analysis for post-development conditions is included in Appendix C. The analysis criteria used for the SCS TR-20 hydraulic analysis of the post-development conditions are as follows:

- Storm Event Frequency: 2, 10, 25, and 50 years.
- SCS Rainfall Distribution: Type III

<u>Storm</u>	<u>(yr, 24-hr)</u>	<u>Rainfall Depth (inches)</u>
2		2.90
10		4.40
25		5.00
50		5.50

- Runoff Coefficients (CN):

>75% grass cover, good, HSG A	= 39
2 acre lots, 12% impervious, HSG A	= 46
1 acre lots, 20% impervious, HSG A	= 51
½ acre lots, 25% impervious, HSG A	= 54
¼ acre lots, 38% impervious, HSG A	= 61
Pavement, roofs, parking lots	= 98

SCS TR-20 Analysis

The post development peak discharges from the subject area for a 2-, 10-, 25-, 50-, and 100-year storm frequency of 24-hour duration are:

Analysis Point	Inflow Area	2-year Storm	10-year Storm	25-year Storm	50-year Storm
	Acres	Flow (cfs)	Flow (cfs)	Flow (cfs)	Flow (cfs)
Design Point 1	9.5	1.5	6.1	9.9	12.4

ANALYSIS SUMMARY

Water Quantity

The pre and post-development peak discharges from the study area for the 2, 10, 25 and 50 year storm frequencies of 24-hour duration for Design Point 1 are compared below:

24 hr Design Storm	Pre Development	Post Development	Difference
	Outflow (cfs)	Outflow (cfs)	Outflow (cfs)
2 yr	0.8	1.5	+0.7
10 yr	5.0	6.1	+1.1
25 yr	7.7	9.9	+2.2
50 yr	10.1	12.4	+2.3

As summarized in the above table, the post-development stormwater flows exceed pre-development flows. Flow attenuation performed through detention or infiltration is not practical at this site due to the shallow groundwater table and the concentrations of gasoline related compounds in the groundwater.

Water Quality Treatment

Stormwater treatment for the proposed site will be provided by deep sumps catch basins and treatment swales as detailed on the design plans.

Temporary Erosion Control

Temporary erosion control measures and their locations are shown on the enclosed Grading, Drainage and Erosion Control Plan and Detail Drawings, and will be included in the construction plans for implementation. Placement of various erosion control devices including silt fences and swales will handle temporary erosion control. Existing drainage structures will be protected with inlet sediment bags. Grass swales will be stabilized with seeding and/or jute mats with check dams employed to detain sediment and reduce velocity.

CONCLUSION

Based on the unavoidable existing conditions of a site that is compromised due to gasoline concentrations in the groundwater, infiltration to the groundwater is not desirable. Groundwater beneath the Whitten Street Park is part of a Groundwater Management Zone described in New Hampshire Department of Environmental Protection Permit # GMP-1984-00003-A-003. Groundwater within this zone may contain dissolved volatile organic compounds at concentrations greater than the ambient water quality criteria. Numerous measures have been implemented to reduce the concentrations of VOCs in soil and groundwater. VOC concentrations in groundwater are decreasing and the size of the dissolved plume is shrinking as biodegradation and other natural attenuation processes occur. Recharge of stormwater on

the Whitten Street Park could influence groundwater resulting in undesirable migration of the plume. Stormwater recharge is also likely to be ineffective because groundwater at the site is close to ground surface, ranging from about 5 feet below ground surface on the eastern portion of the park to only a foot or two beneath the western portion of the park. Any recharge of stormwater would ultimately be captured by the French drain that must be designed to lower the groundwater elevation in the vicinity of the proposed building. There would be no net benefit of recharging storm water that would have to be removed by the French drain.

It is our recommendation that the minor increase in the 10 year storm is left undetained as it leaves the site, and it is our understanding that downstream drainage improvements to the direct receiving system will be made by the Town of Allenstown this year. All runoff from the site will be captured in the closed system and there will not be an increase in stormwater runoff to abutting properties. The new drainage system will replace old closed drainage piping and structures on the site that have been subject to groundwater infiltration. There should be no anticipated or significant downstream impacts expected to the drainage system after these improvements have been implemented.

Custom Soil Resource Report for Merrimack and Belknap Counties, New Hampshire

Custom Soil Resource Report Soil Map

Map Scale: 1:1,690 if printed on A landscape (11" x 8.5") sheet.

Map projection: Web Mercator Corner coordinates: WGS84 Edge tics: UTM Zone 19N WGS84

MAP INFORMATION

The soil surveys that comprise your AOI were mapped at 1:24,000.

Warning: Soil Map may not be valid at this scale.

Enlargement of maps beyond the scale of mapping can cause misunderstanding of the detail of mapping and accuracy of soil line placement. The maps do not show the small areas of contrasting soils that could have been shown at a more detailed scale.

Please rely on the bar scale on each map sheet for map measurements.

Source of Map: Natural Resources Conservation Service
 Web Soil Survey URL: <http://websoilsurvey.nrcs.usda.gov>
 Coordinate System: Web Mercator (EPSG:3857)

Maps from the Web Soil Survey are based on the Web Mercator projection, which preserves direction and shape but distorts distance and area. A projection that preserves area, such as the Albers equal-area conic projection, should be used if more accurate calculations of distance or area are required.

This product is generated from the USDA-NRCS certified data as of the version date(s) listed below.

Soil Survey Area: Merrimack and Belknap Counties, New Hampshire
 Survey Area Data: Version 19, Sep 17, 2014

Soil map units are labeled (as space allows) for map scales 1:50,000 or larger.

Date(s) aerial images were photographed: Apr 8, 2011—May 1, 2011

The orthophoto or other base map on which the soil lines were compiled and digitized probably differs from the background imagery displayed on these maps. As a result, some minor shifting of map unit boundaries may be evident.

Map Unit Descriptions

The map units delineated on the detailed soil maps in a soil survey represent the soils or miscellaneous areas in the survey area. The map unit descriptions, along with the maps, can be used to determine the composition and properties of a unit.

A map unit delineation on a soil map represents an area dominated by one or more major kinds of soil or miscellaneous areas. A map unit is identified and named according to the taxonomic classification of the dominant soils. Within a taxonomic class there are precisely defined limits for the properties of the soils. On the landscape, however, the soils are natural phenomena, and they have the characteristic variability of all natural phenomena. Thus, the range of some observed properties may extend beyond the limits defined for a taxonomic class. Areas of soils of a single taxonomic class rarely, if ever, can be mapped without including areas of other taxonomic classes. Consequently, every map unit is made up of the soils or miscellaneous areas for which it is named and some minor components that belong to taxonomic classes other than those of the major soils.

Most minor soils have properties similar to those of the dominant soil or soils in the map unit, and thus they do not affect use and management. These are called noncontrasting, or similar, components. They may or may not be mentioned in a particular map unit description. Other minor components, however, have properties and behavioral characteristics divergent enough to affect use or to require different management. These are called contrasting, or dissimilar, components. They generally are in small areas and could not be mapped separately because of the scale used. Some small areas of strongly contrasting soils or miscellaneous areas are identified by a special symbol on the maps. If included in the database for a given area, the contrasting minor components are identified in the map unit descriptions along with some characteristics of each. A few areas of minor components may not have been observed, and consequently they are not mentioned in the descriptions, especially where the pattern was so complex that it was impractical to make enough observations to identify all the soils and miscellaneous areas on the landscape.

The presence of minor components in a map unit in no way diminishes the usefulness or accuracy of the data. The objective of mapping is not to delineate pure taxonomic classes but rather to separate the landscape into landforms or landform segments that have similar use and management requirements. The delineation of such segments on the map provides sufficient information for the development of resource plans. If intensive use of small areas is planned, however, onsite investigation is needed to define and locate the soils and miscellaneous areas.

Custom Soil Resource Report

An identifying symbol precedes the map unit name in the map unit descriptions. Each description includes general facts about the unit and gives important soil properties and qualities.

Soils that have profiles that are almost alike make up a *soil series*. Except for differences in texture of the surface layer, all the soils of a series have major horizons that are similar in composition, thickness, and arrangement.

Soils of one series can differ in texture of the surface layer, slope, stoniness, salinity, degree of erosion, and other characteristics that affect their use. On the basis of such differences, a soil series is divided into *soil phases*. Most of the areas shown on the detailed soil maps are phases of soil series. The name of a soil phase commonly indicates a feature that affects use or management. For example, Alpha silt loam, 0 to 2 percent slopes, is a phase of the Alpha series.

Some map units are made up of two or more major soils or miscellaneous areas. These map units are complexes, associations, or undifferentiated groups.

A *complex* consists of two or more soils or miscellaneous areas in such an intricate pattern or in such small areas that they cannot be shown separately on the maps. The pattern and proportion of the soils or miscellaneous areas are somewhat similar in all areas. Alpha-Beta complex, 0 to 6 percent slopes, is an example.

An *association* is made up of two or more geographically associated soils or miscellaneous areas that are shown as one unit on the maps. Because of present or anticipated uses of the map units in the survey area, it was not considered practical or necessary to map the soils or miscellaneous areas separately. The pattern and relative proportion of the soils or miscellaneous areas are somewhat similar. Alpha-Beta association, 0 to 2 percent slopes, is an example.

An *undifferentiated group* is made up of two or more soils or miscellaneous areas that could be mapped individually but are mapped as one unit because similar interpretations can be made for use and management. The pattern and proportion of the soils or miscellaneous areas in a mapped area are not uniform. An area can be made up of only one of the major soils or miscellaneous areas, or it can be made up of all of them. Alpha and Beta soils, 0 to 2 percent slopes, is an example.

Some surveys include *miscellaneous areas*. Such areas have little or no soil material and support little or no vegetation. Rock outcrop is an example.

Soil Information for All Uses

Soil Properties and Qualities

The Soil Properties and Qualities section includes various soil properties and qualities displayed as thematic maps with a summary table for the soil map units in the selected area of interest. A single value or rating for each map unit is generated by aggregating the interpretive ratings of individual map unit components. This aggregation process is defined for each property or quality.

Soil Qualities and Features

Soil qualities are behavior and performance attributes that are not directly measured, but are inferred from observations of dynamic conditions and from soil properties. Example soil qualities include natural drainage, and frost action. Soil features are attributes that are not directly part of the soil. Example soil features include slope and depth to restrictive layer. These features can greatly impact the use and management of the soil.

Hydrologic Soil Group

Hydrologic soil groups are based on estimates of runoff potential. Soils are assigned to one of four groups according to the rate of water infiltration when the soils are not protected by vegetation, are thoroughly wet, and receive precipitation from long-duration storms.

The soils in the United States are assigned to four groups (A, B, C, and D) and three dual classes (A/D, B/D, and C/D). The groups are defined as follows:

Group A. Soils having a high infiltration rate (low runoff potential) when thoroughly wet. These consist mainly of deep, well drained to excessively drained sands or gravelly sands. These soils have a high rate of water transmission.

Group B. Soils having a moderate infiltration rate when thoroughly wet. These consist chiefly of moderately deep or deep, moderately well drained or well drained soils that have moderately fine texture to moderately coarse texture. These soils have a moderate rate of water transmission.

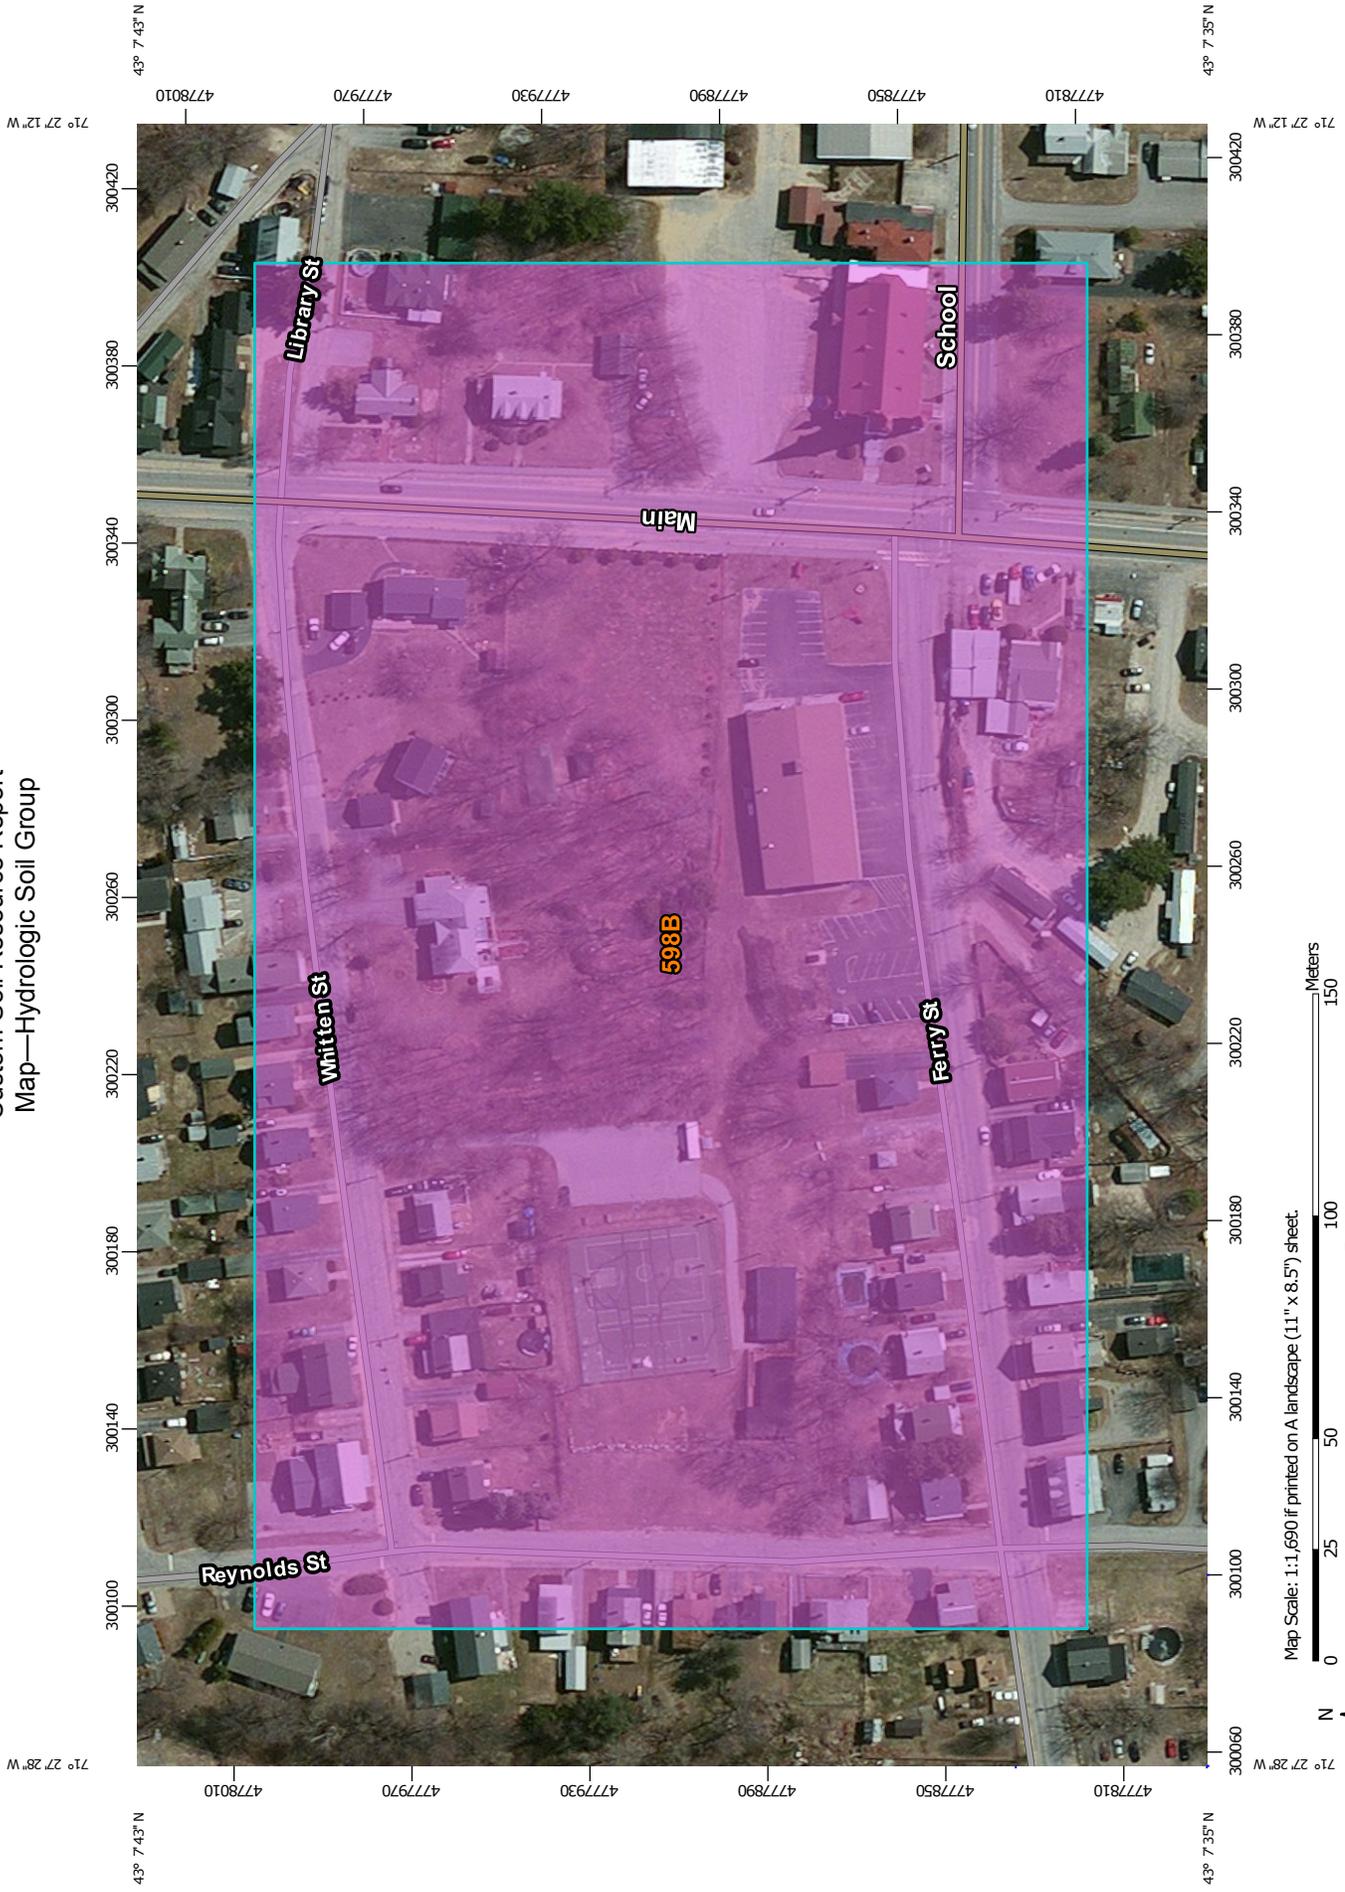

Custom Soil Resource Report

Group C. Soils having a slow infiltration rate when thoroughly wet. These consist chiefly of soils having a layer that impedes the downward movement of water or soils of moderately fine texture or fine texture. These soils have a slow rate of water transmission.

Group D. Soils having a very slow infiltration rate (high runoff potential) when thoroughly wet. These consist chiefly of clays that have a high shrink-swell potential, soils that have a high water table, soils that have a claypan or clay layer at or near the surface, and soils that are shallow over nearly impervious material. These soils have a very slow rate of water transmission.

If a soil is assigned to a dual hydrologic group (A/D, B/D, or C/D), the first letter is for drained areas and the second is for undrained areas. Only the soils that in their natural condition are in group D are assigned to dual classes.
